TRACK 02

EINSTEIN: Science-to-Business Matchmaker

The University of Novi Sad has thousands of researchers and NTP Novi Sad hundreds of companies, yet they rarely work together. Build agents that find the most promising researcher–company pairs and write a concrete proposal for each.

Agents we suggest

The roles below are our suggestion, not a requirement. Split the work however you think is best; what matters is that several agents share it and check each other's work.

Agent	Role
Orchestrator	Takes the task, hands out work, tracks progress, assembles the result.
Research Profiler	Builds researcher profiles from public sources (ORCID, OpenAlex, CORDIS, Google Patents, Lens) or the dataset: fields, skills, projects, patents, each with its source.
Industry Analyst	Pulls each company's technical challenges, needs and direction.
Matchmaker	Ranks pairs and explains each: why these two, and which problem they solve together.
Proposal Writer	Drafts an industrial PhD topic or a one-page joint project for each chosen pair.
Critic	Checks every claim against its source and sends unsupported ones back. Never accepts invented papers or skills.

More ideas: a Funding Scout (open calls such as Horizon Europe or the Innovation Fund), an Outreach agent (an intro email for each pair), Reverse Search (a company describes a

problem, the system finds researchers), or a step where a person approves pairs before the Writer starts.

What you get

A synthetic dataset we made for the hackathon: over a thousand fictional researchers and 150 companies, with 10,000 publications and their abstracts, projects, patents, the companies' challenges, websites and job ads. About 7 million tokens, far more than one model can read at once, so your agents have to split the work. Also a guide to the open APIs, an example of a good industrial PhD topic, and mentors from UNS and NTP throughout.

Dataset ↗ Open APIs ↗ Example PhD topic ↗

Also submit

An architecture diagram, the trace of one full run showing where the Critic stepped in, and at least three proposals for three different pairs. In the README, answer one question: how would this plug into the EINSTEIN network and EINSTEIN Stars?

Data: only public data or the provided dataset. The system proposes collaborations; it never scores or ranks people by worth.

How it's scored

Criterion	Points
Multi-agent architecture: roles, coordination, review loops	30
Proposals a company and a researcher would actually sit down over	25
Accuracy and transparency: sources, trace, no hallucinations	20
Potential for real use in EINSTEIN	15
Responsible use of data	10

For every team

Built on Mozaik. Every track, every team. One agent with a pile of tools doesn't count.

One track per team. You choose it when you submit.

Deadline: Saturday 31 October, 20:00 CET. Resubmit as often as you like; the last entry counts.

Submit: a public GitHub repo with a README: what it does, the architecture, how to run it. No video needed.

Prizes: $500, $300 and $200 for the top three overall, whatever the track. Each entry is scored out of 100 on its track's criteria.

Demos: live at NTP from 17:00, team by team, for anyone who wants to show what they've built so far. Demos are optional; the jury judges every entry from its repo.

Track 01: Software Factory → Track 03: Freestyle →
